Executive Summary

Introduction

The proposed project is the remaining residential phases (Phases 8 through 10) of the Greater Pines Development on Hancock Road in Lake County. This report represents the site specific data, stormwater management data and results of the stormwater analysis.

Phases 1 through 4 have been developed and permitted previously with St Johns Water Management District (SJWMD) under the Individual Permit No. 4-069-0276, issued in January 1993. Phases 5 through 7 have been permitted also under Individual Permit Number 4-069-0276M2, issued September 1997.

The proposed Phases 8 through 10 will occupy approximately 90.17 acres. The development phases are to be developed into single-family residential with an infrastructure road system, stormwater management system and retention ponds. The stormwater management system will be designed according to both Lake County and SJRWMD criteria. This report is intended to supplement a SJRWMD Individual Environmental Resource Permit application for this development.

Existing Stormwater Drainage Conditions

Currently the stormwater runoff from the existing site drains to Lost Lake, a small land-locked lake system. Phases 1 through 7 are collected into existing retention ponds with discharge from those ponds to Lost Lake.

According to SCS Soil Survey for Lake County, the existing soil consists of Chandler Sands, Myakka, and Placid/Myakka, which have hydrologic classification of "A" and "B/D", respectively. Please refer to the geotechnical investigation of the site by Nordarse and Associates under separate attachment, for additional soil details and boring/soil profile information.

Stormwater Management System Design

Hydrologic soil characteristics have been taken from SCS Soil Survey for Lake County to develop runoff numbers outlined in the SCS TR-55 publication. The Time of Concentration for the drainage basin estimated by delineating flow characteristics as overland sheet flow, shallow concentrated flow, or pipe flow, and in accordance with the accepted methods presented in the SCS TR-55 publication.

Three storm events were analyzed as part of this report, as required. Since the percent impervious for the site is less than 50%, no analysis of the mean annual pre/post condition was made. The pre and post development conditions for the 25-year 24-hour 8.6 inch storm event, 25-year 96-hour 11.9 inch storm event, 100-year 24-hour 10.4 inch storm event and the 100-year 96-hour 14.8 inch storm event were analyzed as required by Lake County and SJRWMD.

Storm distributions for the 25/24 and 100/24 the SCS III, and the 25/96 and 100/96 are the SJRWMD96 distribution, as required.

Runoff hydrographs were generated using the Santa Barbara Urban Hydrograph method and flood routed applying the continuity equation through the assistance of the Interconnected Pond Routing computer program (ICPR), version 2.11.

The site discharges to a small land-locked lake, Lost Lake, at the west central side of the site. Due to the land-locked nature of the site, the 25 year 96 hour storm event for the pre and post development conditions was analyzed to determine if there was an increase in the runoff volume from to the proposed development. The on-site retention pond system was designed to hold difference between the pre and post development runoff volumes to assure the discharge to the lake did not increase. Table 1.1 summarizes the results.

Pollution abatement volumes were calculated, and presented herewith, following Lake County and SJRWMD criteria and the ponds analyzed to check for the capacity to receive the volumes and recharge the volumes in the required 72 hours and complete drawdown in 14 days.

Per the site environmentalist, Modica and Associates, for the Phase 5 through 7 permit application, there are approximately 3.6 acres of onsite wetlands in the low depression area (Lost Lake) adjacent to and extending into the Phase 5 through 7 site. No development encroachment within the wetland is proposed.

The stormwater collection system has been designed consisting of pipes, inlets and retention ponds. The system was sized for the 10-year frequency, FDOT Zone 7 Rational Method design. Results from the analysis were used to determine sizes for the pipes, slopes, etc., and are shown on the Construction Plans.

Proposed Stormwater Management System

Pond 2, Pond 3, & Pond 4 – Existing

Ponds 2, 3 and 4 were designed in Phase 5 through 7 development. Some of the proposed development in Phase 8 discharges to this system of ponds. These ponds are interconnected and discharge to a spreader area that ultimately discharges to Lost Lake. These three ponds, their respective drainage basins, along with the previously developed Phases 1 through 4 and their respective stormwater management systems, are incorporated, and presented herewith, to demonstrate conformance with SJRWMD and Lake County criteria.

Pond 5

Pond 5 is located near the southeast side of Lost Lake, near the central west side of the property boundary. It will function as a dry retention system with a top elevation of 92.0 feet and a bottom elevation of 88.0 feet. The soil boring AB41 within the location of Pond 5 showed a vertical permeability of 39 fpd and a high seasonal water table of 85.0

feet. Horizontal permeability typically is 1.5 to 2 times vertical however, per Nodarse soils investigation the average horizontal permeability should be limited to 30 fpd. This pond will overflow through two thirty-foot wide weirs set at elevation 91.0 feet. The routing analysis for Pond 5 indicates a maximum stage of 91.57 feet for the 25/24 design storm event.

Pond 6

Pond 6 is located to the north of Lost Lake, south central area of Phase 9 and 10. It will function as a dry retention system with a top elevation of 92.0 feet and a bottom elevation of 88.0 feet. The soil borings AB37 and AB39 within the location of Pond 6 showed a vertical permeability of 39 and 22 fpd, respectively and a high seasonal water table of 85.0 feet. Horizontal permeability typically is 1.5 to 2 times vertical however, per Nodarse soils investigation the average horizontal permeability should be limited to 30 fpd. This pond will overflow through three twenty-foot wide weirs at elevation 91.0 feet. The routing analysis for Pond 6 indicates a maximum stage of 91.37 feet for the 25/24 design storm event.

TABLE 1.1

SUMMARY OF RESULTS		
GREATER PINES PHASES 8-10		
DESCRIPTION	PRE-DEVELOPED CONDITION	POST-DEVELOPED CONDITION
I. 25-Year 24-Hour Storm Event Runoff Rate Offsite to Lost Lake	389.61 CFS	221.36 CFS
II. 25-Year 96-Hour Storm Event Runoff Volume Offsite to Lost Lake	145.18 AC-FT	130.05 AC-FT
III. 100-Year 96-Hour Storm Event High Water Level in Lost Lake	92.78 FEET	91.93 FEET

SITE AND PROJECT DESCRIPTION

II. Site and Project Description

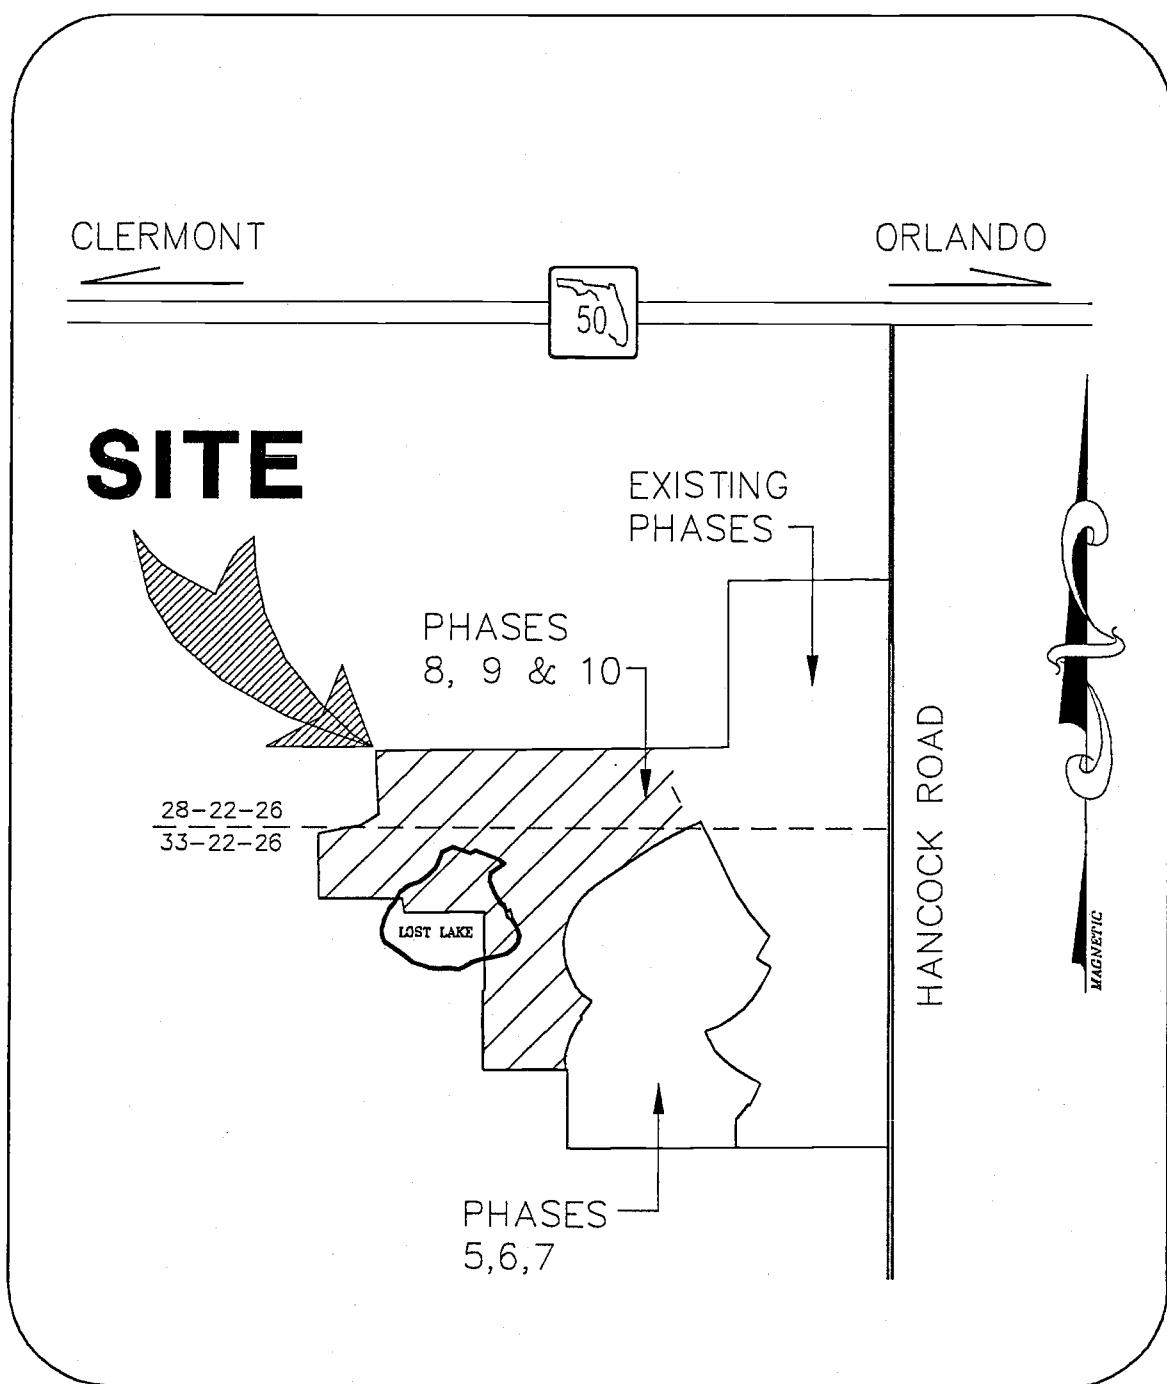

Phases 8 through 10 of the Greater Pines Planned Unit Development consist of approximately 90.17 acres on the west side of the existing Greater Pines PUD. The site is located on Hancock road in south Lake County. A vicinity map is on page 11.

It is proposed to develop the 90.17-acre portion of the PUD into 126 single family homes, with a stormwater collection and retention pond system. Enclosed on page 12 is a depiction of the work proposed. Under a separate attachment are the Construction Plans for the roads, ponds and collection system.

The site is sparse grass and brush covered hilly terrain in the pre-developed condition. Soils are Chandler Sands, Myakka and Placid/Myakks (SCS Type A and B/D, respectively), with high permeability and considerable depth, with the exception being the areas near the lake, to the ground water table. The seasonal high is estimated to be at the elevation of 85.0 feet NGVD. This is the approximate elevation of the 3.6 acres of wetlands along the edge of the lake, as expected.

Presented herewith is an aerial with Phases 8-10 of Greater Pines PUD, as well as the existing phases, overlaid thereon. Pre and Post Development Drainage Basin Maps that depict the development are also presented herewith.

**PRE/POST DEVELOPMENT HYDROLOGIC
ANALYSIS, METHODOLOGY AND RESULTS**

III. Pre/Post Development Hydrologic Analysis, Methodology and Results

Narrative

Pre developed basins as depicted on the Pre Development Drainage Basin Map for Phases 8 through 10 are the same as the Post Development basins for Phases 5 through 7, previously permitted. Pre Development basin areas for on-site and off-site for the entire drainage area contributing to Lost Lake are presented in Table 3.1. Time of Concentrations and curve numbers for the existing Phases 1-4 which are routed through existing Phases 5-7, are depicted in Tables 3A.1, 3C.2 and Tables 3A.2, 3C.3, respectively. For simplicity the Post Development Time of Concentrations and Post Development Curve Numbers from Phases 5-7, have been duplicated and presented herewith to replicate Phase 8 through 10 Pre Development Condition. Tables 3C.2 and 3C.3 show the results of the site specific determinations made for existing pre development site conditions.

Post developed basins as depicted on the Post Development Drainage Basin Maps, have been divided based on topography, cover, curve numbers and the time of concentrations have been estimated. Post Development Basin Areas for on-site and off-site for the entire drainage area contributing to Lost Lake is presented in Table 3.2. Time of Concentration and curve numbers for the proposed Phases 8-10 are shown in Tables 3.3, 3.4 and 3.5.

The time of concentration for each basin has been developed using the methodology outlined in SCS TR-55. The first 300 feet of travel is modeled as overland flow using the

$$T_c = \frac{0.007(n*L)^{0.8}}{(P_2)^{0.5} s^{0.4}}$$

following equation:

Where: T_c = Time of concentration in hours

n = the roughness coefficient as provided in Table 3.1 of SCS TR-55

L = The distance traveled in feet

P_2 = The 2 year 24 hour rainfall volume in inches

s = The slope of the hydraulic grade line (land slope)

For any distance traveled beyond 300 feet, on an unpaved surface, the time of

$$T_c = \frac{L}{(16.1345)s^{0.4}}$$

concentration is estimated using shallow concentrated flow as follows:

Where: T_c = Time of concentration in seconds

L = The distance traveled in feet

s = The slope of the hydraulic grade line (land slope)

For any distance traveled beyond 300 feet, on a paved surface, the time of concentration

$$T_c = \frac{L}{(20.3282)s^{0.4}}$$

is estimated using shallow concentrated flow as follows:

Where: T_c = Time of concentration in seconds

L = The distance traveled in feet

s = The slope of the hydraulic grade line (land slope)

In the post development condition, the site is divided into runoff basins as depicted on the Post Development Drainage Basin Map. The percent impervious, and its division into Directly Connected Impervious Area (DCIA) and Non Directly Connected Impervious Area (NDCIA), estimated for this analysis is shown on the Typical Lot Layout, page 27. The results are shown in Table 3.4, DCIA & NDCIA Table Basin Analysis on page 28.²⁹ Curve numbers are then calculated using SCS Methods as outlined in the TR-55. The results for the post-developed condition curve numbers are shown in Table 3.5.³⁰

TOTALS 138.98 11.18 5.12 16.30 122.68

NOTES:

1. DCIA = DIRECTLY CONNECTED IMPERVIOUS AREA, i.e. IMPERVIOUS AREA DIRECTLY CONNECTED TO THE STORM DRAINAGE SYSTEM WITHOUT FLOW OVER ANY PVIOUS AREA.
2. NDCIA = IMPERVIOUS AREA NOT DIRECTLY CONNECTED TO THE STORM SYSTEM, BUT WHICH DISCHARGES OVER A PVIOUS AREA PRIOR TO ENTRY INTO THE STORM DRAINAGE SYSTEM.
3. AREA OF IMPERVIOUS = DCIA + NDCIA.
4. PERCENT DCIA COMPUTED BY DIVIDING AREA DCIA BY THE TOTAL BASIN AREA.
5. SCS "CN" FOR PVIOUS AND NDCIA COMPUTED BY DIVIDING THE SUM OF THE PRODUCTS OF THE PVIOUS AREA TIMES A CN OF 39 AND THE NDCIA AREA TIMES A CN OF 95, BY THE SUM OF THE SAME TWO AREAS.

NOTES:

- a) L₁-G, S₁-G & T₁-G ARE LENGTH, SLOPE AND COMPUTED TIME OF TRAVEL FOR RUNOFF OVER GRASS IN 1ST 300 FT, USING SHEET FLOW FORMULAE FROM SCS TR55.
- b) L₁-C, S₁-C & T₁-C ARE LENGTH, SLOPE AND COMPUTED TIME OF TRAVEL FOR RUNOFF OVER PAVED IN 1ST 300 FT, USING SHEET FLOW FORMULAE FROM SCS TR55.
- c) L₂-G & T₂-G ARE LENGTH AND COMPUTED TIME OF TRAVEL FOR RUNOFF OVER GRASS IN REMAINING PATH LENGTH WHERE V=16.1345*(S^{0.5})^{0.5} (PER TR-55 PAGE F-1).
- d) L₂-C & T₂-C ARE LENGTH AND COMPUTED TIME OF TRAVEL FOR RUNOFF OVER PAVED IN REMAINING PATH LENGTH WHERE V=20.3282*(S^{0.5})^{0.5} (PER TR-55 PAGE F-1).
- e) TRAVEL TIME (T_t) IS THE SUM OF TIME FOR FIRST 300 FT PLUS TIME FOR REMAINING PATH OR 10 MINUTE MINIMUM PER FDOT.

$$T_{1-C\&G} = \{0.007(nL)^{0.8}/((P)^{0.5}(s)^{0.4})\}$$

Where:

T = Time (hrs)

L = Length (ft)

s = slope (ft/ft)

P = 2yr - 24hr Rainfall (in)

n = Manning's roughness coefficient

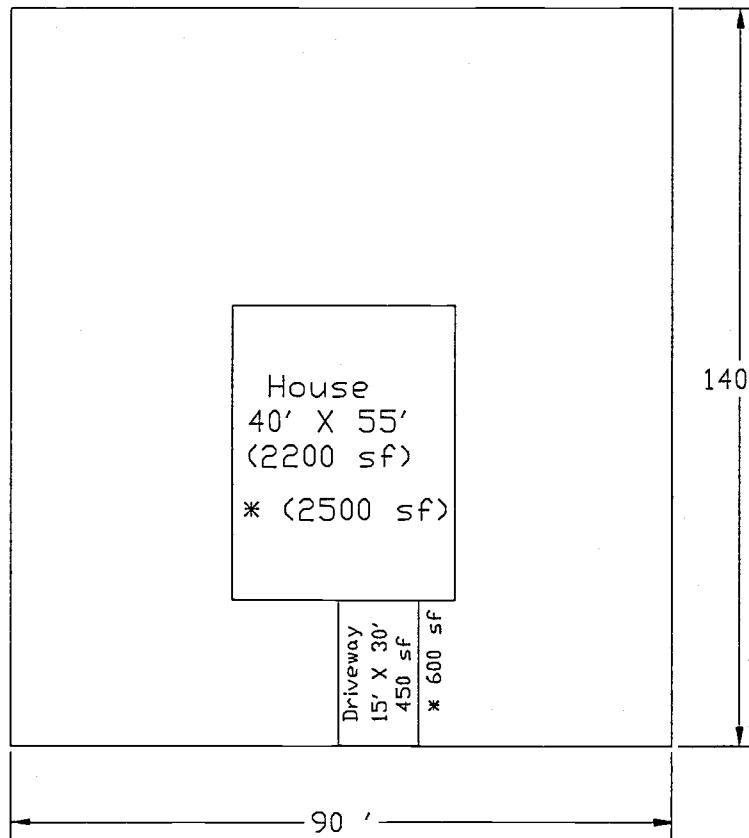

Assumptions:

n = 0.011 for concrete

n = 0.15 for grass

P = 4.92 in.

retention 12.79 AC
TOTAL 285.42 AC

PROJECT 90.17 AC

* FOR 15-1 ACRE LOTS - BASIN 10-1

IMPERVIOUS(DCIA)= 100% of Roads + 50% of Sidewalks + 45% of lot impervious area
%DCIA= (DCIA)/(total area)*100

IMPERVIOUS(NDCIA) = 50% Of sidewalks + 55% of lot impervious area

PERVIOUS AREA = total area - Impervious DCIA - Impervious NDCIA

COMPOSITE CN =imp NDCIA * 95 + retention*39 + (perVIOUS-retention) * 48
/ NDCIA + (perVIOUS-retention) + retention

%IMPERVIOUS = ((0.883 + 0.750)/10.00) * 100 = 16.34%

SAMPLE CALCULATION:

BASIN 8-1

IMPERVIOUS (DCIA) = 0.261*1 + 0.095*0.5 + (1.06+0.22)*45 = 0.883 AC

%DCIA = (0.883/10.0)*100 = 8.83%

IMPERVIOUS(NDCIA) = 0.095*0.5 + (1.06+0.22)*0.55 = 0.750 AC

PERVIOUS AREA = 10.00 - 0.883 - 0.750 = 8.36 AC

COMPOSITE CN = 0.750 *95 + 0*39 + (8.36)*48 / 0.750 + 8.36 = 52

%IMPERVIOUS = ((0.883 + 0.750)/10.00) * 100 = 16.34%

NOTES:

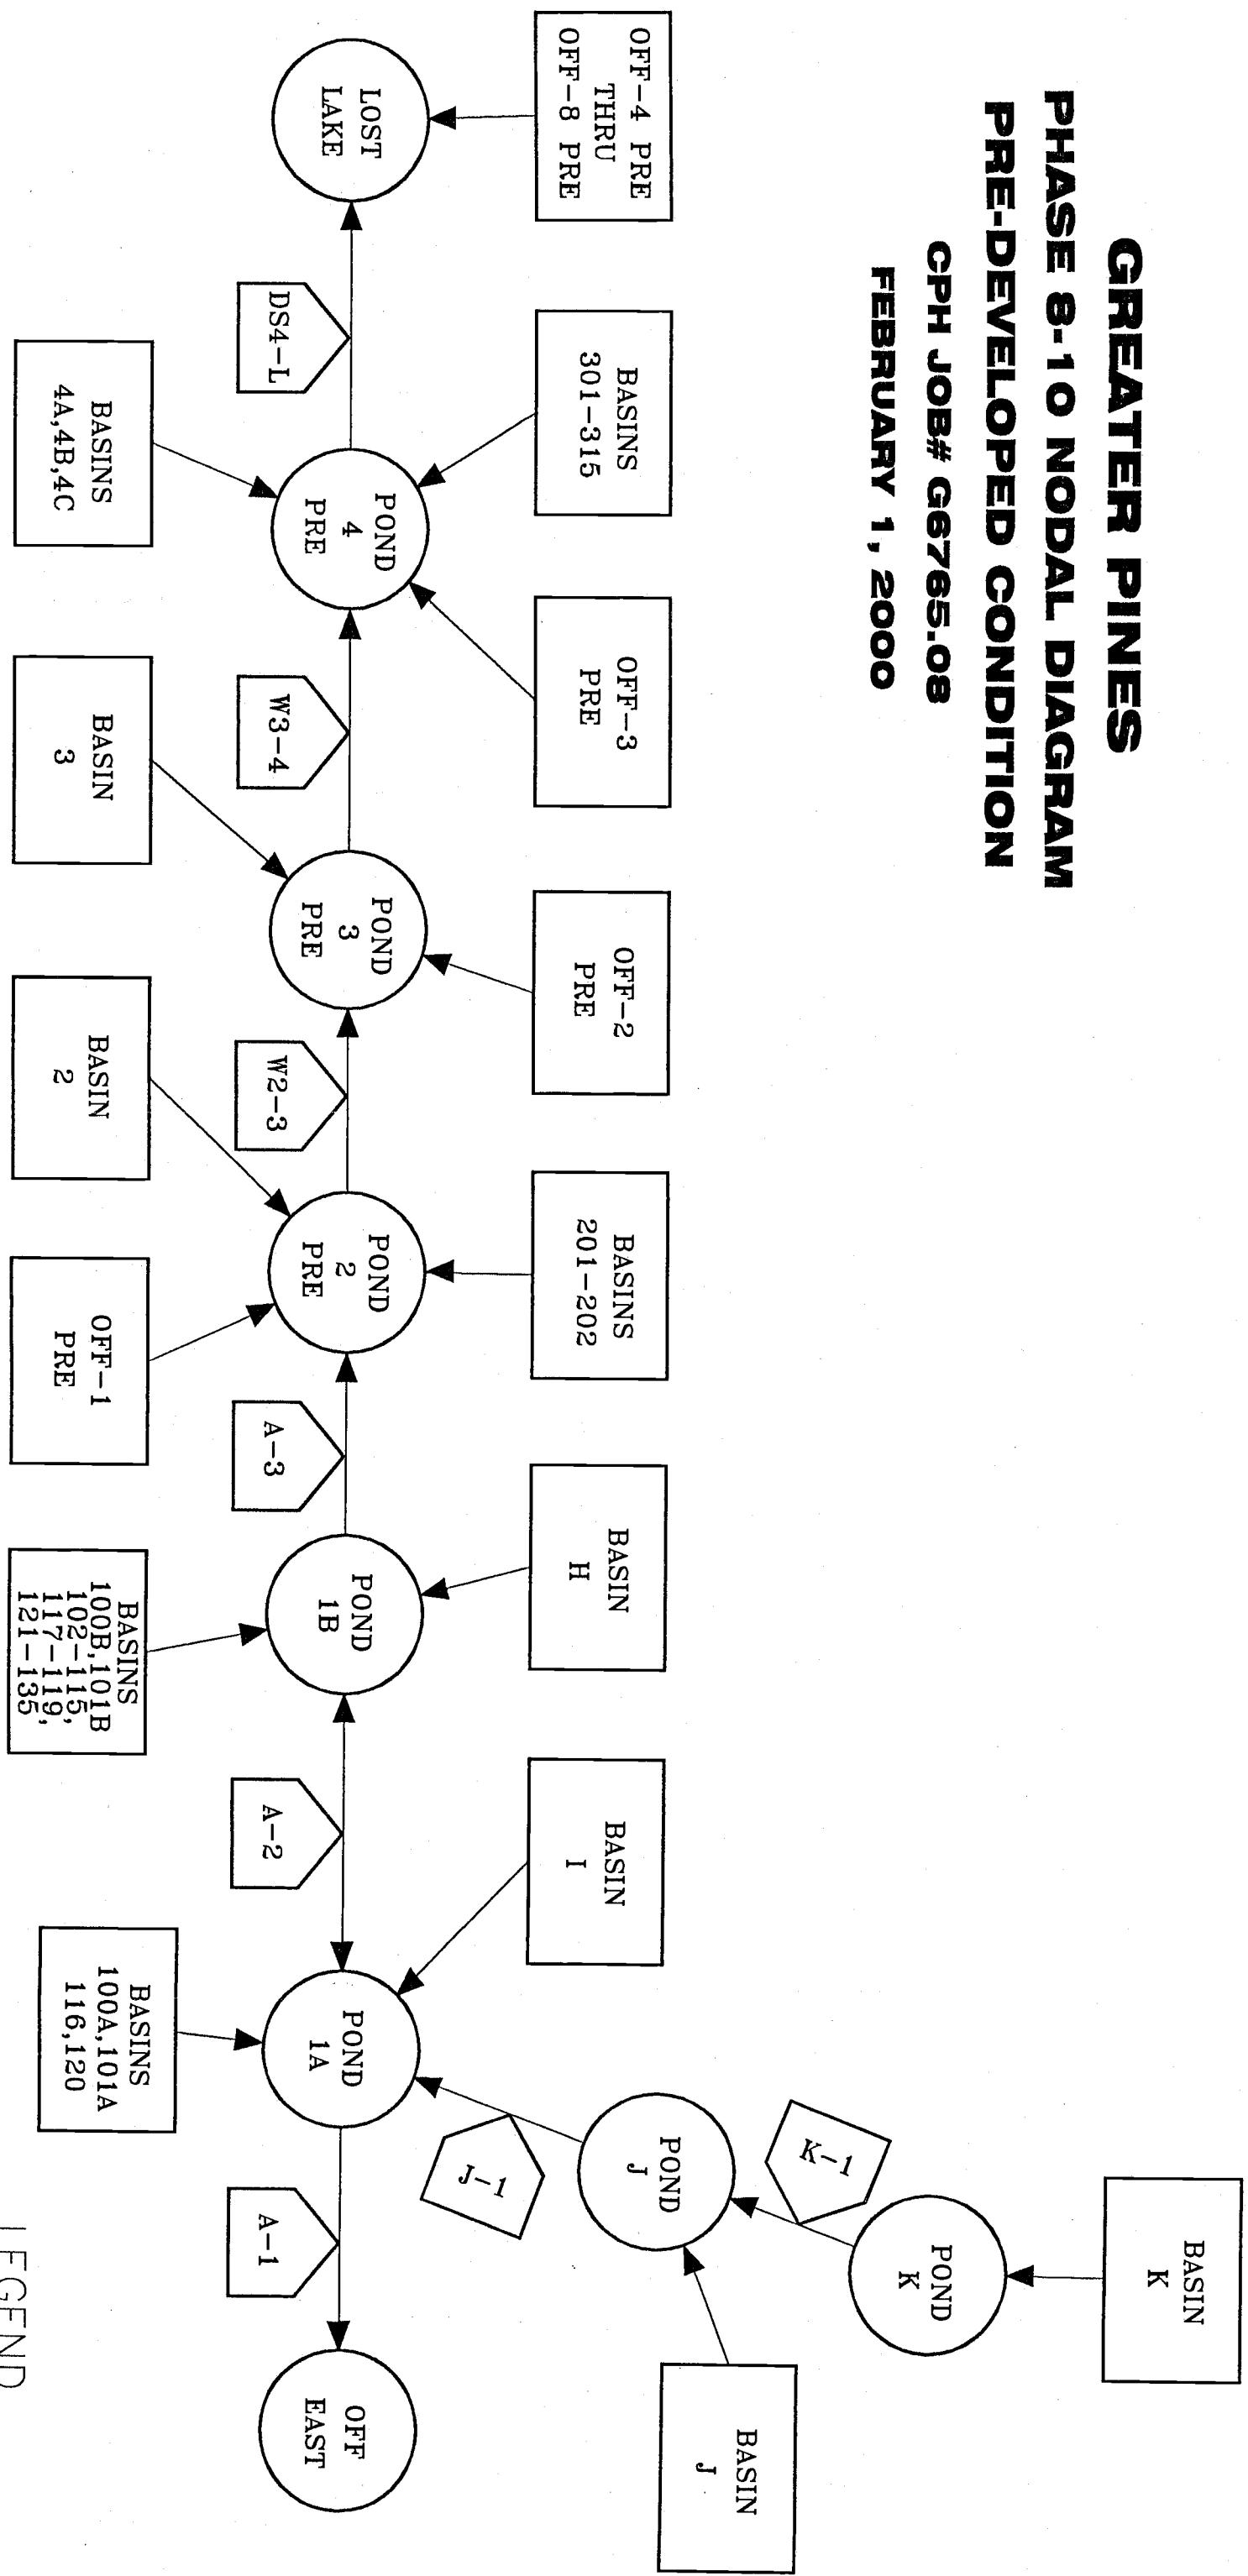

1. DCIA = DIRECTLY CONNECTED IMPERVIOUS AREA,
i.e. IMPERVIOUS AREA DIRECTLY CONNECTED TO THE
STORM DRAINAGE SYSTEM WITHOUT FLOW OVER
ANY PERVERSUS AREA.
2. NDCIA = IMPERVIOUS AREA NOT DIRECTLY CONNECTED
TO THE STORM SYSTEM, BUT WHICH DISCHARGES OVER
A PERVERSUS AREA PRIOR TO ENTRY INTO THE STORM
DRAINAGE SYSTEM.
3. AREA OF IMPERVIOUS = DCIA + NDCIA.
4. PERCENT DCIA COMPUTED BY DIVIDING AREA DCIA
BY THE TOTAL BASIN AREA.
5. SCS "CN" FOR PERVERSUS AND NDCIA COMPUTED BY
DIVIDING THE SUM OF THE PRODUCTS OF THE PERVERSUS
AREA TIMES IT'S CN AND THE NDCIA AREA TIMES IT'S
CN, BY THE SUM OF THE SAME TWO AREAS.

**POLLUTION ABATEMENT
AND RECOVERY**

V. Pollution Abatement and Recovery

Pollution abatement volume (PAV) has been provided in the proposed retention ponds 5 and 6 for the portions of the site to be developed as either residential, roadway, developed open area, or the retention ponds themselves. Tables 5.1 and 5.2 show the calculations used to decide the pollution abatement volumes for each drainage basin. The pollution abatement volume for Phases 5-7 are shown in Table 5.1 and for Phases 8-10 are shown in Table 5.2. Table 5.3 summarizes the Total Pollution Abatement Volumes. This analysis does not take into account the soakage/spreader ponds drawdown. This volume is taken into the retention ponds (Ponds 2,3,4,5&6) and the retention pond volumes were then investigated to insure the ponds would hold the entire abatement volume without an overflow. Table 5.4 and 5.5 shows the Post Development Retention Pond Stage/Area and Storage Volume. In addition, soakage swales/ponds have been included as part of the retention system to enhance water quality of Lost Lake, however, these swales/ponds have not been included in the pollution abatement recovery analysis.

The pollution abatement volume was again investigated to insure the volume in the retention ponds would recharge within the 72-hour period regulation. Drawdown was done for each retention pond using Modret. Parameters used in the model were obtained from the soil report done by Nodarse and Associates, included herewith as separate attachment. The pollution abatement drawdown results from the Modret analysis for each retention pond are enclosed.

WETLANDS

VI. Wetlands

Modica and Associates made an on-site determination of wetlands during permitting for Phase 5 through 7. The wetlands have been surveyed and are shown on the construction plans, and consist of approximately 3.6 acres of herbaceous wetland. We are not proposing any development or impact of this wetland area.

**FLOOD PRONE COMPENSATING
STORAGE ANALYSIS**

VII. Flood Prone Compensating Storage Analysis

The following calculations are intended to demonstrate there will be no adverse impacts to drainage or flood protection to offsite or adjacent property. These calculations demonstrate that the total runoff from the development into Lost Lake has been reduced enough to compensate for loss of storage volume in the 100-year flood prone. Attached as Table 7.1 shows the Stage/Area/Storage Summary for Lost Lake. Additionally, portions of the USGS Flood Prone Area Map with the site overlaid and the FEMA map with the site overlaid have been enclosed as Figures 7.1 and 7.2. The FEMA map depicts the area as Zone A, which does not have an elevation determined. The USGS Flood Prone areas Map shows contours. The 100-year flood prone elevation has been estimated from the USGS Flood Prone Map in the pre-developed condition to be 92.0.

The 100-year 96-hour flood event was run on the pre development condition model, taking into account all the basins that contribute to Lost Lake and calculated a flood prone of 92.78, confirming the USGS Flood Prone Map.

In the post developed condition the 100-year 96-hour flood event was modeled. The model showed the flood prone in the post condition in Lost Lake of 91.93, below the pre condition and matching the USGS Flood Prone.

Table 7.

NOTES:

1. DCIA = DIRECTLY CONNECTED IMPERVIOUS AREA,
i.e. IMPERVIOUS AREA DIRECTLY CONNECTED TO THE
STORM DRAINAGE SYSTEM WITHOUT FLOW OVER
ANY PERVIOUS AREA.
2. NDCIA = IMPERVIOUS AREA NOT DIRECTLY CONNECTED
TO THE STORM SYSTEM, BUT WHICH DISCHARGES OVER
A PERVIOUS AREA PRIOR TO ENTRY INTO THE STORM
DRAINAGE SYSTEM.
3. IMPERVIOUS AREAS HAVE A "C" VALUE OF 0.9 & PERVIOUS
AREAS ARE GIVEN A "C" VALUE OF 0.2.

Table 2-2a.—Runoff curve numbers for urban areas¹

Cover type and hydrologic condition	Average percent impervious area ²	Curve numbers for hydrologic soil group—			
		A	B	C	D
<i>Fully developed urban areas (vegetation established)</i>					
Open space (lawns, parks, golf courses, cemeteries, etc.) ³ :					
Poor condition (grass cover < 50%)	68	79	86	89	
Fair condition (grass cover 50% to 75%)	49	69	79	84	
Good condition (grass cover > 75%)	39	61	74	80	
Impervious areas:					
Paved parking lots, roofs, driveways, etc. (excluding right-of-way)	98	98	98	98	
Streets and roads:					
Paved; curbs and storm sewers (excluding right-of-way)	98	98	98	98	
Paved; open ditches (including right-of-way)	83	89	92	93	
Gravel (including right-of-way)	76	85	89	91	
Dirt (including right-of-way)	72	82	87	89	
Western desert urban areas:					
Natural desert landscaping (pervious areas only) ⁴ ...	63	77	85	88	
Artificial desert landscaping (impervious weed barrier, desert shrub with 1- to 2-inch sand or gravel mulch and basin borders)	96	96	96	96	
Urban districts:					
Commercial and business	85	89	92	94	95
Industrial	72	81	88	91	93
Residential districts by average lot size:					
1/8 acre or less (town houses)	65	77	85	90	92
1/4 acre	38	61	75	83	87
1/3 acre	30	57	72	81	86
1/2 acre	25	54	70	80	85
1 acre	20	51	68	79	84
2 acres	12	46	65	77	82
<i>Developing urban areas</i>					
Newly graded areas (pervious areas only, no vegetation) ⁵		77	86	91	94
Idle lands (CN's are determined using cover types similar to those in table 2-2c).					

¹Average runoff condition, and $I_a = 0.2S$.²The average percent impervious area shown was used to develop the composite CN's. Other assumptions are as follows: impervious areas are directly connected to the drainage system, impervious areas have a CN of 98, and pervious areas are considered equivalent to open space in good hydrologic condition. CN's for other combinations of conditions may be computed using figure 2-3 or 2-4.³CN's shown are equivalent to those of pasture. Composite CN's may be computed for other combinations of open space cover type.⁴Composite CN's for natural desert landscaping should be computed using figures 2-3 or 2-4 based on the impervious area percentage (CN = 98) and the pervious area CN. The pervious area CN's are assumed equivalent to desert shrub in poor hydrologic condition.⁵Composite CN's to use for the design of temporary measures during grading and construction should be computed using figure 2-3 or 2-4, based on the degree of development (impervious area percentage) and the CN's for the newly graded pervious areas.

Sheet flow

Sheet flow is flow over plane surfaces. It usually occurs in the headwater of streams. With sheet flow, the friction value (Manning's n) is an effective roughness coefficient that includes the effect of raindrop impact; drag over the plane surface; obstacles such as litter, crop ridges, and rocks; and erosion and transportation of sediment. These n values are for very shallow flow depths of about 0.1 foot or so. Table 3-1 gives Manning's n values for sheet flow for various surface conditions.

For sheet flow of less than 300 feet, use Manning's kinematic solution (Overton and Meadows 1976) to compute T_t :

$$T_t = \frac{0.007 (nL)^{0.8}}{(P_2)^{0.5} s^{0.4}} \quad [\text{Eq. 3-3}]$$

Table 3-1.—Roughness coefficients (Manning's n) for sheet flow

Surface description	n^1
Smooth surfaces (concrete, asphalt, gravel, or bare soil)	0.011
Fallow (no residue)	0.05
Cultivated soils:	
Residue cover $\leq 20\%$	0.06
Residue cover $> 20\%$	0.17
Grass:	
Short grass prairie	0.15
Dense grasses ²	0.24
Bermudagrass	0.41
Range (natural)	0.13
Woods: ³	
Light underbrush	0.40
Dense underbrush	0.80

¹The n values are a composite of information compiled by Engman (1986).

²Includes species such as weeping lovegrass, bluegrass, buffalo grass, blue grama grass, and native grass mixtures.

³When selecting n , consider cover to a height of about 0.1 ft. This is the only part of the plant cover that will obstruct sheet flow.

where

T_t = travel time (hr),
 n = Manning's roughness coefficient (table 3-1),
 L = flow length (ft),
 P_2 = 2-year, 24-hour rainfall (in), and
 s = slope of hydraulic grade line (land slope, ft/ft).

This simplified form of the Manning's kinematic solution is based on the following: (1) shallow steady uniform flow, (2) constant intensity of rainfall excess (that part of a rain available for runoff), (3) rainfall duration of 24 hours, and (4) minor effect of infiltration on travel time. Rainfall depth can be obtained from appendix B.

Shallow concentrated flow

After a maximum of 300 feet, sheet flow usually becomes shallow concentrated flow. The average velocity for this flow can be determined from figure 3-1, in which average velocity is a function of watercourse slope and type of channel. For slopes less than 0.005 ft/ft, use equations given in appendix F for figure 3-1. Tillage can affect the direction of shallow concentrated flow. Flow may not always be directly down the watershed slope if tillage runs across the slope.

After determining average velocity in figure 3-1, use equation 3-1 to estimate travel time for the shallow concentrated flow segment.

Open channels

Open channels are assumed to begin where surveyed cross section information has been obtained, where channels are visible on aerial photographs, or where blue lines (indicating streams) appear on United States Geological Survey (USGS) quadrangle sheets. Manning's equation or water surface profile information can be used to estimate average flow velocity. Average flow velocity is usually determined for bank-full elevation.

LAKE COUNTY
MAP SYMBOLS
(CONVERSION LEGEND)

The first capital letter is the initial one of the map unit name. The second capital letter, A, B, C, D, E or F shows the class of slope. Symbols without a slope letter identify nearly level soils.

**RE: Report of Subsurface Exploration and
Geotechnical Engineering Evaluation
Greater Pines Subdivision, Phases 8, 9 and 10
Lake County, Florida**

Dear Mr. Gregg:

Nodarse & Associates, Inc. (N&A) is pleased to present this report of our subsurface exploration and geotechnical engineering evaluation for the above-referenced project. This exploration was performed in general accordance with our proposal dated November 17, 1999. The purposes of this study were to explore subsurface conditions at the site and to use the data obtained to develop engineering recommendations to guide site preparation and design of roadways, septic systems and stormwater retention facilities. This report describes our exploration procedures, exhibits the data obtained and presents our conclusions and recommendations regarding the geotechnical engineering aspects of site development.

SITE AND PROJECT DESCRIPTION

The project is located in Sections 28 and 33, Township 22 South, Range 26 East in Lake County, Florida. More specifically, the site is located north and east of Lost Lake and adjacent to Phase 6 of the Greater Pines Subdivision. It is N&A's understanding that roadways, retention ponds and septic systems are proposed at the above-referenced site. This proposal is based on your memorandum dated November 11, 1999.

Based on the United States Geological Survey (USGS) quadrangle map and the site plan you provided, ground surface elevations at the site range from about +85 to almost +200 feet. The lower ground surface elevations are near Lost Lake and several high ridges are present, primarily in the north portion of the site. Consequently, based on this review and your memorandum dated November 11, 1999, we anticipate that fairly significant cutting

BUILD ON OUR EXPERIENCE

and filling will occur at the site. Your memorandum indicates that most of the cutting will occur in the north portion of the site. The quadrangle map indicates that the area surrounding Lost Lake was primarily used as citrus groves in the past.

We also reviewed the USDA Soil Conservation Service (SCS) Lake County soil survey. This survey indicates that the majority of the soils are upland soils with relatively deep groundwater levels except for those adjacent to Lost Lake. These soils are still considered sandy soils with groundwater levels within 1 foot of the existing ground surface.

AREA GEOLOGY

The geology of the Central Florida area is characterized by sedimentary strata formed during three distinct geologic periods. The surficial stratum is composed of undifferentiated Holocene/ Pleistocene/Pliocene age sands, containing varying amounts of silt and clay, which extend typically to depths on the order of 40 to 60 feet below ground surface. This upper, mostly sandy zone contains the surficial (water table) aquifer. A Miocene age deposit, the Hawthorne Formation, frequently underlies the surficial sand and is typically composed of clay, clayey sands and sandy limestone containing appreciable amounts of phosphate. This relatively impermeable stratum extends to typical depths of 125 to 150 feet beneath ground surface and serves as the confining layer for the underlying Floridan aquifer. The Floridan aquifer, composed of Eocene age Ocala, Avon Park and Lake City Limestones, is one of the most productive aquifers in the world. The extremely high productivity of this aquifer is directly related to its ubiquitous cavities and interconnected channels, some being more than 100 feet in height. These cavities were formed by dissolution of the limestone caused by the movement of slightly acidic water through the rock.

The geology of the area, as described above, is conducive to the development of sinkholes. The solution features within the limestone can collapse or can allow the downward movement of overlying soils, known as ravelling, to produce depressions at the surface which are typically circular in shape (sinkholes). Sinkholes can occur nearly anywhere in Central Florida, but are more likely to occur in areas characterized by thin confining beds, large differences between the water table elevation and the Floridan aquifer potentiometric level and the presence of limestone in relatively close proximity to the ground surface. However, the probability of a sinkhole occurring within a relatively small site, even in an area regarded as a "high risk area" with regard to sinkhole activity, is very low. A comprehensive sinkhole risk evaluation for the site was not within the scope of this study. However, N&A could provide these services if you so desire.

SUBSURFACE EXPLORATION

The subsurface exploration for this study consisted of performing twenty-six (26) auger borings ranging in depth from 7 to 25 feet within the proposed roadway, fourteen (14) auger borings ranging in depth from 10 to 25 feet within the proposed residential lots and seven (7) auger borings to a depth of 15 feet within the proposed stormwater retention areas. Three (3) relatively undisturbed soil samples were obtained from the stormwater retention areas for laboratory permeability testing. The borings were located in the field by referencing prominent site features, estimating right angles and taping from these features. The approximate boring locations can be found on **Figure 1** in the **Appendix**.

The machine auger borings were performed by hydraulically turning a 4 inch diameter continuous flight auger into the ground in 5 foot increments. Additional flights were added until the desired termination depth was achieved. The auger was then extracted without further rotation and representative soil samples were retrieved from the auger. Samples were visually classified in the field and were then packaged and returned to our soils laboratory for further classification and testing.

The hand auger boring procedure consisted of manually turning a 3 inch diameter, 6 inch long sampler into the soil until it was full. The sampler was then retrieved and the soils in the sampler were visually examined and classified. The procedure was repeated until the desired termination depth was achieved or shallow groundwater levels caused collapse of the borehole. Samples of representative strata were obtained for further visual examination and classification in our laboratory.

LABORATORY TESTING

Wash Sieve No. 200 grain size analyses were performed on selected soil samples obtained during the subsurface exploration to assist in visual classification of the soil. Permeability testing was performed on relatively undisturbed soil samples obtained from the borings performed within the proposed stormwater retention areas. The results of the laboratory testing are shown adjacent to the boring soil profiles on **Figures 2 through 4** in the **Appendix** at the appropriate depths from which the soil samples were taken.

GENERAL SUBSURFACE CONDITIONS

Subsurface conditions encountered in the borings are shown on **Figures 2 through 4** in the **Appendix**. Descriptions of the soils encountered in the borings are accompanied by the Unified Soil Classification symbol (SP, SC, etc.) based on visual examination. Stratification boundaries between soil types should be considered approximate as the actual transition between soil types may be gradual.

Roadways: In general, the borings performed within the proposed roadway locations encountered the following generalized soil profile: Orangish-brown fine sand (SP) (Stratum 1) with intermittent layers of orangish-brown slightly silty fine sand (SP-SM) (Stratum 2) from the existing ground surface to the boring termination depths ranging from 7 to 25 feet below the existing ground surface.

Notable exceptions to this profile were found at Borings AB-9, AB-11, AB-33 and AB-35. These borings encountered a layer of orangish-brown slightly clayey fine sand (SP-SC) (Stratum 3). For the approximate elevation of Stratum 3, please reference the **Boring Soil Profile Sheet (Figures 2 and 3)** in the **Appendix**.

Lots and Stormwater Ponds: The auger borings performed within the pond locations and the residential lots encountered orangish-brown fine sand and slightly silty fine sand (SP) (SP-SM) (Strata 1 and 2) from the existing ground surface to the boring termination depths of 10 to 25 feet. Borings AB-30, AB-32 and AB-34 encountered a layer of orangish-brown slightly clayey fine sand (SP-SC) (Stratum 3) at varying depths. Please reference the **Boring Soil Profile Sheet (Figure 2)** in the **Appendix** for the approximate elevation of Stratum 3.

GROUNDWATER

Borings AB-1 through AB-35 and HA-1 through HA-5 did not encounter groundwater during our field exploration. Borings AB-36 through AB-42 encountered groundwater at approximately 79 to 81 feet NGVD. These borings encountered groundwater due to their close proximity to the existing Lost Lake. Based on the USGS quadrangle map, SCS soil survey and borings performed for this study, the seasonal high groundwater level is dependent upon the operating level of Lost Lake. We estimate that the seasonal high groundwater level for this site to be approximately +85 feet NGVD in the vicinity of Lost Lake. Although none of the other borings encountered groundwater, the groundwater level likely rises above +85 feet NGVD in topographically higher areas of the site. However, changes in drainage characteristics due to site development or the installation and operation of irrigation systems may cause significant deviations from this anticipated estimated seasonal high groundwater level.

CONCLUSIONS AND RECOMMENDATIONS

The following conclusions and recommendations are based on the project characteristics previously described, the data obtained in our field exploration and our experience with similar subsurface conditions and construction types. If final roadway alignments or grades are significantly different from those previously described in this report, or if subsurface conditions different from those disclosed by the borings are encountered during

construction, we should be notified immediately so that we might review and modify, if necessary, the following recommendations in light of such changes.

General Roadway Subgrade Preparation: The initial step in routine roadway subgrade preparation should be the complete removal of all topsoil, trees, major root systems and other deleterious materials from beneath and to 5 feet beyond proposed pavement areas. Based on the boring results, stripping thicknesses are not expected to exceed 6 inches at this site. However, in areas of existing trees and major root systems, stripping thickness may be deeper.

After this initial stripping process, the entire site should be inspected by a geotechnical engineer. At that time, the exposed subgrade should be proofrolled using a large vibratory roller (Dynapac CA-25 or equivalent). The vibratory roller should be operated in "static mode" within 100 feet of existing structures. Proofrolling of the pavement areas should consist of at least ten (10) overlapping passes along the roadway alignment and should be observed by a geotechnical engineer. The purposes of the proofrolling will be to detect any areas where unsuitable soils are present as well as to densify the near-surface loose soils for support of shallow foundations. Materials which yield excessively during the proofrolling should be undercut and replaced with well-compacted structural fill. The geotechnical engineer, based on observations at the site, can recommend the nature and extent of any remedial work. Based on our exploration, no major remedial work is anticipated at this site.

Proofrolling of the pavement areas should continue for the required number of passes and until the soil at a depth of 12 inches below the compaction surface has attained a minimum of 95% of the soil's modified Proctor maximum dry density as determined by AASHTO Specification T-180. In-place density tests should be performed by an experienced geotechnical engineering technician working under the direction of a registered geotechnical engineer to verify the required degree of compaction. A test frequency of at least one (1) test per 300 lineal feet of alignment proofrolled is recommended.

Fill Placement: After the exposed subgrade has been proofrolled and accepted by the geotechnical engineer, any fill required to bring the roadway to final grade may be placed and properly compacted. All fill should be inorganic, non-plastic, granular soil (clean sands) (Strata 1 and 2). The fill should be placed in level lifts not to exceed 12 inches loose thickness if the compactor recommended above to proofroll the site is also used to compact the fill. The fill should be compacted to a minimum of 95% of the soil's modified Proctor maximum dry density as determined by AASHTO Specification T-180. In-place density tests should be performed on each lift by an experienced engineering technician working under the direction of a registered geotechnical engineer to verify that the recommended degree of compaction has been achieved. We suggest a minimum testing

frequency of one (1) test per lift per 300 lineal feet of alignment. This fill should extend a minimum of 5 feet beyond pavement areas to prevent possible erosion or undermining of the pavements. Further, fill slopes should not exceed 2 horizontal to 1 vertical. All fill placed in utility line trenches and should also be properly placed and compacted to the specifications stated above. However, in these restricted working areas, compaction should be accomplished with lightweight, hand-guided compaction equipment and lift thicknesses should be limited to a maximum of 4 inches loose thickness.

Pavement Grading Recommendations: Based on the soil and groundwater conditions encountered during our field exploration, it appears that soil conditions are suitable for conventional flexible or semi-flexible pavement construction using the standard Lake County minimum sections following normal site preparation. Either a limerock or soil-cement base may be used if a minimum separation of 18 inches is provided between the bottom of the base and the estimated seasonal high groundwater table. If a lesser separation is provided, a soil-cement base should be used. The owner may wish to consider that shrinkage and cracking of soil-cement is normal, and that it may not provide an as aesthetically pleasing finished product as limerock. If grades provide a separation of less than 12 inches between the bottom of the base and the estimated seasonal high groundwater levels, underdrains will be required. However, due to groundwater levels encountered, it does not appear that underdrains will be required. Subgrade preparation, base and asphaltic concrete construction should be according to Lake County and local municipality standards.

Stormwater Management Facilities: As mentioned previously, the soil conditions encountered in the retention pond areas were generally fine sand (SP) and slightly silty fine sand (SP-SM). Groundwater levels were encountered during our field exploration at elevations between +79 and +81 feet NGVD. The estimated seasonal high groundwater level is approximately +85 feet NGVD. Based on the soil and groundwater conditions encountered during our field exploration, dry retention systems may be feasible depending upon final pond design.

Laboratory permeability testing was performed on relatively undisturbed soil samples obtained during the field exploration. The vertical coefficients of permeability obtained from these tests are as follows: (Note: All pond locations are referenced in regard to Lost Lake).

- 39 feet per day for Boring AB-37 in the location of the northwestern pond area.
- 22 feet per day for Boring AB-39 in the location of the northeastern pond area.
- 39 feet per day for Boring AB-41 in the location of the southeastern pond area.

Experience in similar soil types indicates that the horizontal permeability is typically in the range of 1.5 to 2 times the vertical permeability rate. However, we recommend using a limiting average horizontal permeability rate of 30 feet per day for design of both pond areas. We would be pleased to perform stormwater recovery analyses for the proposed ponds once final pond design is available.

On Site Disposal Systems: In general, the site appears suitable for the use of individual on site disposal systems (septic tank/drainfield). However, the northwest portion of the site may require additional preparation due to a moderately limiting soil layer of orangish-brown slightly clayey fine sand (SP-SC) (Stratum 3) encountered in this area.

Based on the Florida Department of Health guidelines, drainfields located within a moderately limited soil such as Stratum 3 must either be over-excavated or designed with a lower loading rate. In both cases, the seasonal high groundwater levels must be at least 24 inches below the bottom surface of the drainfield.

If these areas are over-excavated, there must be at least 54 inches between the bottom of the proposed bed and the moderately limited layer (Stratum 3). Also the area must be over-excavated 2 feet wider and longer than the proposed bed. If the moderately limited soil (Stratum 3) is replaced with slightly limited soil (Stratum 1), the maximum allowable loading rate is 0.70 gallons per square foot per day.

If over-excavation is not feasible, then the bed must be designed with a slower maximum allowable loading rate. For the moderately limited soil at this site (Stratum 3), the maximum allowable loading rate is 0.35 gallons per square foot per day.

The following minimum distances should also be considered when locating and installing the on site disposal system:

- 75 feet from private potable wells.
- 100 feet from public drinking water well if such well serves a facility with an estimate sewage flow of 2,000 gallons or less per day.
- 200 feet from public drinking water well if such well serves a facility with an estimate sewage flow of more than 2,000 gallons per day.
- 50 feet from non-potable water well.
- 10 feet from any storm sewer pipe.

- 15 feet from design high-water line of retention areas, detention area or swales designed to contain standing or flowing water for less than 72 hours after rainfall or the design high-water level of normally dry drainage ditches or normally dry individual-lot stormwater retention areas.
- 10 feet from potable water lines unless such lines are sealed with a waterproof sealant within a sleeve.
- 75 feet from the near high water line of lakes, streams, canals, normally wet drainage ditches and retention areas designed to contain standing or flowing water for 72 hours or more following a rainfall.

Although on site disposal systems should be feasible at this site, designers should consider final grades in relation to the on site disposal systems. Relatively steep grades may allow for sewage effluent to seep onto adjacent lots and roadways, especially in areas of heavy cuts. The relatively sandy soils encountered in our borings (Strata 1 and 2) should allow for natural infiltration of the effluent and reduce the amount of seepage or runoff onto adjacent properties. However, severe cuts into or near Stratum 3 (slightly clayey fine sand) could allow for seepage of effluent.

Alternatives to lessen these effects would be to reduce grades in such areas, over size drainfield areas and/or use of cutoff trenches. We would be pleased to provide further assistance, if you so desire.

CLOSURE

The recommendations provided above are based on widely spaced borings. This report does not reflect variations in soil conditions between or away from the boring locations. The nature and extent of the variations between the borings may not become evident until during construction. If such variations are encountered during construction, N&A should be informed and given an opportunity to re-evaluate the recommendations above after performing on-site observations during the construction period and noting the characteristics of the variations.
